This means that all nodes can share an absolute reference time.

2.3.3.1.4.1. Running Node Sequence The node that transmits the control packet generates a random number, and transmits the unique running node number (identifier) and a timestamp in a packet sequence. The first node that receives this sequence will record this identifier and timestamp in its node log. Any node that receives a sequence also saves the identifier and timestamp received. This node now has a timestamp and a running node number to make a new routing discovery. 2.3.3.1.4.2. Routing Discovery The node that receives the control packet transmits a number of beacon packets. Each beacon packet has a unique identifier. The node that receives the beacon packet that has the highest identifier will set its own identifier to the identifier of the beacon packet, and its timestamp to the timestamp of the beacon packet. This node is now the "pivot node", and can communicate with all other nodes in the network.

2.3.3.1.5. Network Management The control packet format has a field called "management command". This field a1d647c40b
